Many materials have a well-characterized refractive index, but these indexes often depend strongly upon the frequency of light, causing optical dispersion.Standard refractive index measurements are taken at the "yellow doublet" sodium D line, with a wavelength of 589 nanometers. There are also weaker dependencies on temperature, pressure/stress, etc., as well on precise material compositions ...

The optics of the lens change via UV-sensitive macromers that, when stimulated, polymerize and thicken the intraocular lens where needed. For example, if a patient ended up hyperopic post-cataract surgery, the LDD would be programmed to photopolymerize the central portion of the lens, thereby thickening and increasing the power of the lens.

1) Note that Equation (1) does not describe a traveling wave. At any position x , y (x , t) simply oscillates in time with an amplitude that varies in the x -direction as $2 y_{\max} \sin \left(2\pi x \over \lambda \right)$. The animation at the beginning of this article depicts what is happening. As the left-traveling blue wave and right ...
